ABSTRACT- *Agriculture plays a vital role in the economy and food security of many countries. Paddy is one of the most important staple crops cultivated worldwide. Accurate crop detection and appropriate soil recommendation are essential for improving yield and reducing losses. Traditional farming practices rely heavily on farmer experience and manual observation. These methods may lead to inefficient resource usage and reduced productivity. Artificial Intelligence provides advanced solutions for smart agriculture. This project focuses on paddy crop detection and soil recommendation using AI techniques. Image processing and machine learning models are used to detect paddy crop conditions. Soil parameters such as moisture, pH, and nutrient content are analyzed. The system recommends suitable soil treatments and fertilizers. Data is collected from sensors and crop images. AI models process this data for accurate prediction. The system supports early detection of crop issues. It*

helps farmers make informed decisions. Automation reduces manual effort. The approach improves crop yield and soil health. The system is scalable and cost-effective. It promotes sustainable farming practices. The proposed solution demonstrates the effectiveness of AI in agriculture.

KEYWORDS: - *Convolutional Neural Networks, Deep Learning, soil suggestion, paddy crop colour images, Computer Vision, AI*

INTRODUCTION

Agriculture is the backbone of rural economies and a primary source of livelihood. Paddy cultivation requires specific soil and environmental conditions. Improper soil management can reduce crop yield significantly. Farmers often face challenges in identifying crop health and soil suitability. Traditional methods are time-consuming and less accurate. The advancement of Artificial Intelligence has transformed agricultural practices. AI

enables precise crop monitoring and soil analysis. Crop detection using image processing helps identify growth stages and diseases. Soil recommendation systems guide farmers on nutrient management. Machine learning models analyze large agricultural datasets. These technologies improve decision-making in farming. Smart agriculture reduces wastage of water and fertilizers. It increases productivity and profitability. This project aims to develop an AI-based system for paddy crop detection. It also recommends suitable soil treatments. The system integrates crop image analysis and soil data. Real-time monitoring enhances efficiency. The solution supports sustainable agriculture. It reduces dependency on expert intervention. This project contributes to intelligent farming solutions.

RELATED WORK

Several research studies have focused on applying Artificial Intelligence and deep learning techniques in agriculture for crop monitoring and soil analysis. Early approaches used machine learning algorithms such as Support Vector Machines (SVM), Decision Trees, and Random Forest for crop disease detection based on leaf image features. With advancements in deep learning, Convolutional Neural Networks (CNNs) have been widely adopted for accurate

identification of crop diseases and classification of plant conditions. Researchers have demonstrated that CNN-based models can effectively detect paddy diseases such as blast, leaf spot, and bacterial blight with high precision. In parallel, soil suitability prediction has been addressed using sensor-based systems and machine learning models that analyze parameters like pH, moisture, and nutrient levels. IoT-based frameworks have been developed to collect real-time soil data and provide recommendations for fertilizers and crop selection. Some studies have integrated weather data with soil analysis to enhance prediction accuracy. Precision agriculture techniques using drones and satellite imagery have also been explored for large-scale crop monitoring. However, most existing systems focus on either crop detection or soil analysis independently.

LITERATURE SURVEY

The literature survey Several research studies have explored the application of Artificial Intelligence and machine learning techniques in agriculture, particularly for crop disease detection and soil analysis. Traditional machine learning algorithms such as Support Vector Machines (SVM), K-Nearest Neighbors (KNN), Decision Trees, and Random Forest have been used to identify diseases from leaf images. Recent advancements highlight the use of

Convolutional Neural Networks (CNNs), which automatically extract features and provide higher accuracy in detecting paddy diseases like blast and brown spot. In parallel, soil analysis systems use sensors and IoT technologies to monitor parameters such as moisture, temperature, and pH levels in real time. Machine learning models are applied to recommend suitable crops and fertilizers based on soil conditions. Precision agriculture techniques using drones, GPS, and satellite imagery help in large-scale monitoring and early disease detection. Mobile-based applications further assist farmers by providing real-time recommendations through image uploads. However, most existing systems focus on either crop disease detection or soil analysis independently. Limitations such as dataset constraints, environmental variability, and computational complexity affect performance. Overall, existing research shows strong potential for AI in agriculture but highlights the need for an integrated, scalable, and cost-effective solution for paddy crop management.

EXISTING METHOD

The existing paddy farming system relies on traditional agricultural practices. Farmers depend on experience and manual inspection. Crop health is visually monitored. Soil quality is assessed through

conventional testing. These methods are time-consuming and costly. Accuracy depends on farmer knowledge. Early detection of crop stress is difficult. Soil nutrient deficiencies may go unnoticed. Existing digital tools provide limited automation. Crop detection systems are not widely adopted. Soil recommendation systems are mostly rule-based. Integration between crop and soil analysis is lacking. Real-time monitoring is minimal. Data collection is often manual. Environmental factors are not accurately analyzed. Existing systems lack scalability. Advanced AI techniques are rarely used. Visualization and decision support are limited. Farmers receive delayed recommendations. Overall efficiency remains low.

PROPOSED METHOD

The proposed system introduces an AI-based solution for paddy crop detection and soil recommendation. Crop images are captured using cameras or mobile devices. Image preprocessing enhances image quality. Deep learning models detect paddy crop condition and growth stages. Soil sensors collect data such as moisture, pH, and nutrients. Machine learning models analyze soil data. The system recommends suitable fertilizers and soil treatments. Crop and soil data are integrated for better decision-making. The system provides real-time insights. Automated analysis reduces

manual effort. The model improves accuracy and efficiency. Farmers receive timely recommendations. The system supports sustainable farming. Cloud deployment enables scalability. User-friendly interfaces improve accessibility. The solution reduces resource wastage. It enhances crop yield. Ethical data handling is ensured. The system adapts to different farming conditions. This approach modernizes paddy cultivation using AI.

SYSTEM ARCHITECTURE

Figure 1: Architecture of the Project
METHODOLOGY DESCRIPTION

Data Collection Data Collection: Data collection is the initial step in developing the AI-based paddy detection system. Images of paddy crops are collected from various sources, including datasets and field surveys. These images cover different growth stages and disease conditions. Soil parameters such as moisture, pH, and

nutrients are also gathered using sensors or reports. This step ensures the availability of quality data for accurate model training.

Data Preprocessing: Data preprocessing prepares the collected data for efficient model training. Images are resized, normalized, and cleaned to maintain consistency across the dataset. Data augmentation techniques such as rotation and flipping are applied to increase diversity. Missing soil values are handled appropriately to maintain data integrity. This step improves model accuracy and prevents overfitting.

Data Visualization: Data visualization helps in understanding patterns and distributions within the dataset. Charts such as histograms and bar graphs are used to analyze crop classes and soil parameters. Visualization tools help identify data imbalance and inconsistencies. Sample images are displayed to verify labeling correctness. This step provides better insights for improving model performance.

Model Creation and Training (CNN): In this stage, a Convolutional Neural Network (CNN) model is designed and trained. The model extracts features such as texture and patterns from paddy images. Training is performed using labeled data with multiple epochs and validation checks. Techniques like dropout and optimization improve accuracy and reduce overfitting. This step builds the core intelligence of the system.

Prediction and Result Display (Flask Integration): The system allows users to upload paddy images through an HTML interface. The uploaded image is preprocessed and passed to the trained CNN model. The model predicts crop condition and possible diseases. Based on soil data, recommendations for fertilizers and treatment are provided. Results are displayed using Flask, enabling real-time and user-friendly interaction.

RESULTS AND DISCUSSION

This project shows the details of profile how we can detect easily.

Figure 2.1: Login Page

In this picture we showed login page of the project in these basic details we can get.

Figure 2.2: Home Page

Here we can see home page. The we will start detection process.

Figure 2.3: Upload Input

If we clicked then browse input image and upload it.

Figure 2.4: Detect Paddy Crop with Soil Suggestions Basmati

Finally, after uploading input image it can detect paddy type and it will give soil suggestions like above.

CONCLSUION

The proposed Smart Paddy Identification and Soil Suitability Prediction system demonstrates the effective use of Artificial Intelligence in agriculture. By integrating deep learning for crop detection and machine learning for soil analysis, the system provides accurate and reliable predictions. It reduces manual effort and supports early detection of crop diseases, improving productivity. The system promotes efficient use of resources such as water and fertilizers. Overall, it offers a

scalable, cost-effective, and sustainable solution for modern smart farming.

FUTURE SCOPE

Future enhancements can include integration of real-time weather data to improve prediction accuracy. The system can be extended to support multiple crops beyond paddy for wider applicability. Advanced technologies such as drones and satellite imaging can be used for large-scale monitoring. Mobile based application development can improve accessibility for farmers in rural areas. Additionally, incorporating IoT automation and cloud-based systems can transform it into a fully intelligent smart agriculture platform.
